

Genome Structural Variation

Evan Eichler

Howard Hughes Medical Institute

University of Washington

January 18th, 2024, Genomics Workshop, Český Krumlov

Genetic Variation

Types

- Single base-pair changes – point mutations
- Small insertions/deletions– frameshift, microsatellite, minisatellite
- Mobile elements—retroelement insertions (300bp -10 kb in size)
- Large-scale genomic variation (>1 kb)
 - Large-scale Deletions, Inversion, translocations
 - Segmental Duplications
- Chromosomal variation—translocations, inversions, fusions.

Sequence

Cytogenetics

Genome Structural Variation

Deletion

Duplication

Inversion

Introduction

- **Genome structural variation** : gains and losses of DNA (copy-number variation (CNV)) as well as balanced events such as inversions and translocations—operationally defined >50 bp
- **Objectives**
 1. Genomic architecture and disease impact.
 2. Detection and characterization methods
 3. Primate genome evolution

Copy number polymorphism in *Fcgr3* predisposes to glomerulonephritis in rats and humans

Perspective: Segmental Duplications (SD)

Definition: Continuous portion of genomic sequence represented more than once in the genome ($>90\%$ and $> 1\text{kb}$ in length)—historical copy number variation

Importance:

SDs promote genome structural variation

Importance: Evolution of New Gene Function

GeneA

Mutation

Maintain old
Function

Duplication

Acquire New/
Modified Function

Mutation

GeneA'

Mutation

Loss of Function

Human Genome Segmental Duplication Pattern

Mouse Segmental Duplication Pattern

- 118 Mb or ~4% dup
- >20 kb, >95%
- 89% are tandem
- Gene/transcript poor
- Associated with LINEs

Human Segmental Duplications Properties

- Large (>10 kb)
- Recent (>95% identity)
- **Interspersed (60% are separated by more than 1 Mb)**
- Modular in organization
- Difficult to resolve

Rare Structural Variation & Disease

•**Genomic Disorders:** A group of diseases that results from genome rearrangement mediated mostly by non-allelic homologous recombination. (*Inoue & Lupski , 2002*).

DiGeorge/VCF/22q11 Syndrome

A Normal heart

B Heart with tetralogy of Fallot

1/2000 live births
180 phenotypes
75-80% are sporadic (not inherited)

Human Genome Segmental Duplication Map

- 130 candidate regions (298 Mb)
- 23 associated with genetic disease
- Target patients array CGH

Chromosome 17

Chromosome 15

Chromosome 15

Genome Wide CNV Burden

(15,767 cases of ID,DD,MCA vs. 8,328 controls)

Common and rare structural variation are linked 17q21.31 deletion syndrome

Chromosome 17

17q21.31 inversion

- Region of recurrent deletion is a site of common inversion polymorphism in the human population
- Inversion is largely restricted to Caucasian populations
 - 20% frequency in European and Mediterranean populations
- **Inversion is associated with increase in global recombination and increased fecundity**

b

A common inversion polymorphism

- Tested 17 parents of children with microdeletion and found that every parent within whose germline the deletion occurred carried an inversion
- Inversion polymorphism is a risk factor for the microdeletion event

Duplication Architecture of 17q21.31 Inversion (H2) vs. Direct (H1) Haplotype

- Inversion occurred 2.3 million years ago and was mediated by the LRRC37A core duplicon
- H2 haplotype acquired human-specific duplications in direct orientation that mediate rearrangement and disrupts *KANSL1* gene

Zody *et al.*, *Nat. Genet.* 2008, Itsara *et al.*, *Am J. Human Genet* 2012

Summary

- Human genome is enriched for segmental duplications which predisposes to recurrent large CNVs during germ-cell production
- 15% of neurocognitive disease in intellectual disabled children is “caused” by CNVs—8% of normals carry large events
- Segmental duplications enriched 10-25 fold for structural variation.
- Increased complexity is beneficial and deleterious: Ancestral duplication predisposes to inversion polymorphism, inversion polymorphisms acquires duplication, haplotype becomes positively selected and now predisposes to microdeletion

II. Genome-wide SV Discovery Approaches

Hybridization-based

- Iafrate et al., 2004, Sebat et al., 2004
- SNP microarrays: McCarroll *et al.*, 2008, Cooper *et al.*, 2008, Itsara *et al.*, 2009
- Array CGH: Redon *et al.* 2006, Conrad *et al.*, 2010, Park *et al.*, 2010, WTCCC, 2010

Single molecule mapping

- Optical mapping: Teague et al., 2010 e.g. Bionano Genomics: Levy-Sakin et al, 2019

Sequencing-based

- Read-depth: Bailey et al, 2002
- Fosmid ESP: Tuzun *et al.* 2005, Kidd *et al.* 2008
- Next-gen sequencing: Korbel *et al.* 2007, Yoon *et al.*, 2009, Alkan et al., 2009, Chen *et al.* 2009; Mills 1000 Genomes Project, 2011, Sudmant *et al.* 2015a,
- Long-read Sequencing: Chaisson *et al.*, 2015, 2019, Pendleton *et al.*, 2015, Sedlazeck et al., 2018 Audano *et al.*, 2019, Ebert et al., 2021

Array Comparative Genomic Hybridization

← 12 mm →

One copy gain = $\log_2(3/2) = 0.57$ (3 copies vs. 2 copies in reference)

One-copy loss = $\log_2(1/2) = -1$

SNP Microarray detection of Deletion (Illumina)

Using sequence read pairs to resolve structural variation

Dataset: 1,122,408 fosmid pairs preprocessed (15.5X genome coverage)
639,204 fosmid pairs BEST pairs (8.8 X genome coverage)

Genome-wide Detection of Structural Variation (>8kb) by End-Sequence Pairs

Tuzun et al, *Nat. Genetics*, 2005; Kidd et al., *Nature*, 2008

Next-Generation Sequencing Methods

- **Read pair analysis**
 - Deletions, small novel insertions, inversions, transposons
 - Size and breakpoint resolution dependent to insert size
- **Read depth analysis**
 - Deletions and duplications only
 - Relatively poor breakpoint resolution
- **Split read analysis**
 - Small novel insertions/deletions, and mobile element insertions
 - 1bp breakpoint resolution
- **Local and *de novo* assembly**
 - SV in unique segments
 - 1bp breakpoint resolution

Using Sequence Read Depth

- Map whole genome sequence to reference genome
 - Variation in copy number correlates linearly with read-depth

Personalized Duplication or Copy-Number Variation Maps

Venter (Sanger)

Watson (454)

NA12878 (Solexa)

NA12891 (Solexa)

NA12892 (Solexa)

•Two known ~70 kbp CNPs, CNP#1 duplication absent in Venter but predicted in Watson and NA12878, CNP#2 present mother but neither father or child

Alkan, Nat. Genet, 2009

Read-Depth CNV Heat Maps vs. FISH

Interphase FISH

Indirect sequence-based approaches are incomplete

159 genomes (2-4X) (deletions only)

Mills *et al.*, Nature 2011

Challenges

- Size spectrum—>5 kbp discovery limit for most experimental platforms; NGS can detect much smaller but misses events mediated by repeats.
- Class bias: deletions>>> duplications>>>> balanced events (inversions)
- Multiallelic copy number states—incomplete references and the complexity of repetitive DNA
- False negatives.

Long read Genome Sequencing Revolution

Pacific Biosciences (PacBio)—single-molecule real-time sequence (SMRT) data (15-50) kbp sequence reads
ONT (Oxford Nanopore Technology)—higher error rate but, portable, scalable native DNA sequencing of long-reads

Advances in long-read sequencing

HiFi Pac Bio Sequencing

99.9% accurate 18-23 kbp reads

Ultra-long reads ONT

>100 kbp in length

Advantages of long read sequencing

Ultra-long Oxford Nanopore Technology (ONT)
~139 kbp

HiFi PacBio
~18-20 kbp

Illumina
150-300 bp

More uniform coverage and sequencing of native DNA

SHANK3

PacBio
Sequence
Coverage

Illumina
Sequence
Coverage

Increased sensitivity for structural variation (SV)

- ~25,000 PacBio SVs vs. 11,000 Illumina SVs >50 bp
- Eleven Illumina callers combined detect 49% of deletions and 11% of insertions in a human genome--**NGS misses 75% of SVs**

LRS has transformed how we characterize copy number and structural variation

2015

2023

Complete sequence of human genome

2021 (T2T-CHM13)

So how did we do it?

We used an *effectively haploid* human cell line known as CHM13

CHM13 is a complete hydatidiform mole

This greatly simplifies this problem because it allows us to assemble each chromosome without interference from a second set of chromosomes

We used two long-read sequencing technologies with complementary strengths

1. Pacific Biosciences (PacBio) high-fidelity (HiFi)

- 15-25 kbp long
- >99% accurate (similar to Illumina)
- Strength: Extremely accurate

2. Oxford Nanopore Technologies (ONT)

- No limit in read length!
- 93-99% accurate
- Strength: Extremely long

AAAS

FILLING THE GAPS

Closing in on a complete
human genome p. 42

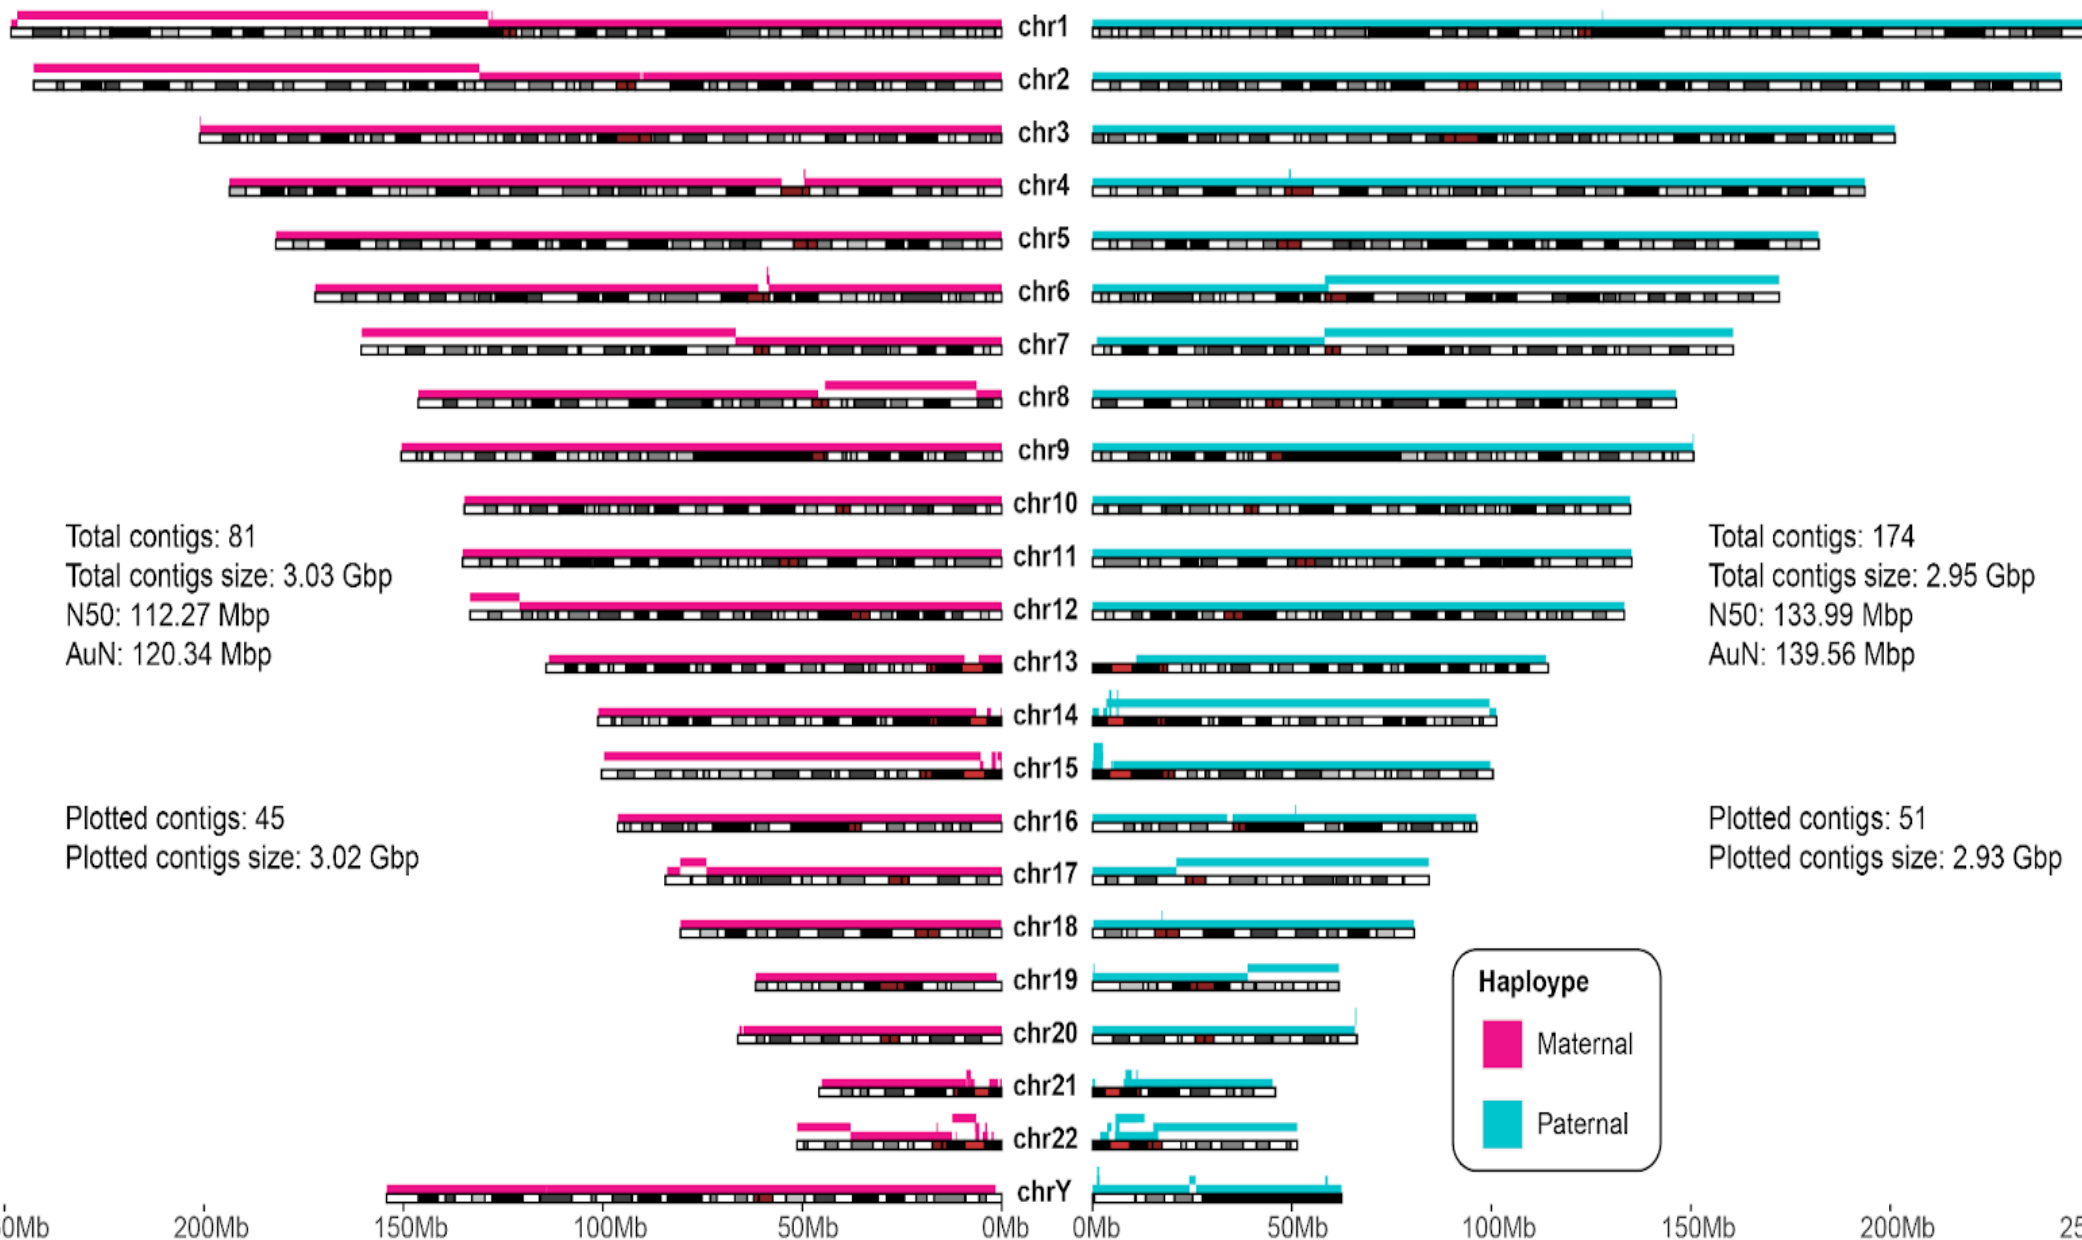

- 8% of missing genome sequence added (>200 Mbp)
- Complete sequence of centromeres, acrocentric and segmental duplications
- Adds 1956 gene predictions of which 130-190 are protein coding
- Framework for understanding the genetically most complex regions of our genome.

A 6 Gbp Human Genome Assembly (contig N50=25-28 Mbp)

Porubsky et al, Nat. Biotech, 2020

Trio-based verkko assemblies of HG002

Primate phased genome assembly efforts

Complete sequencing of ape chromosomes

Chromosome 12

DongAhn Yoo & the T2T Primates Consortium

Complete sequencing of ape chromosomes (SVbyEye)

DongAhn Yoo unpublished

A graph can capture such variation e.g. Minigraph

1. Generate phase genome assemblies
2. Iteratively introduce assembly sequence to a graph.
3. Distinguish query sequence already present in graph from novel sequence
4. Include novel sequence as new segments or edges between segments in graph.
5. Repeat with next assembly

A graph-based representation of structural variation

A graph-based representation of the entire human genome as a conceptual new reference.

Summary

- Short read NGS approaches
 - Multiple methods are needed—readpair+read-depth+splitread often with orthogonal validation such as SNP microarray
 - ~75% of SVs are missed because SVs are non-randomly distributed to repetitive regions where mapping quality is low
 - Read-depth approaches allow CNV prediction but not structure
- Long-read sequencing methods provide complete SV but currently limited throughput
 - Read-based versus assembly-based approaches
 - Telomere-to-telomere assemblies of human genomes now possible or nearly so for diploid—**complete genetic information where all variants are phased.**
 - First human pangenome now available—a new concept to eventually replace a singular reference.

III. Why?

- Ohno—Duplication is the primary force by which new gene functions are created
- There are 990 annotated genes completely contained within segmental duplications

Dynamic Genetic Variation

- Genomic copy number changes contributes more genetic difference between apes and humans than SNVs
- 468 Mbp CNV vs. 167 Mbp SNVs (ration: 2.8)

Rate of Duplication

$p=9.786 \times 10^{-12}$

Mosaic Architecture

- A mosaic of recently transposed duplications
- Duplications within duplications.
- Potentiates “exon shuffling”, regulatory innovation

Human Chromosome 16 Core Duplicon

- The burst of segmental duplications 8-12 mya corresponds to core-associated duplications which have occurred on six human chromosomes (chromosomes 1,2, 7, 15, 16, 17)

- Most of the recurrent genomic disorders associated with developmental delay, epilepsy, intellectual disability, etc. are mediated by duplication blocks centered on a core.

Human/Great-ape “Core Duplicons” have led to the emergence of new genes

TRE2

NPIP

NBPF

LRRC37A

RGPD

Features: No orthologs in mouse; multiple copies in chimp & human
dramatic changes in expression profile; signatures of positive selection

Core Duplicon Hypothesis

The selective disadvantage of interspersed duplications is offset by the benefit of evolutionary plasticity and the emergence of new genes with new functions associated with core duplicons.

Marques-Bonet and Eichler, CSHL *Quant Biol*, 2008

Human-specific gene family expansions

Notable human-specific expansion of brain development genes.

Neuronal cell death: $p=5.7e-4$; Neurological disease: $p=4.6e-2$

Sudmant et al., *Science*, 2010

SRGAP2 function

- *SRGAP2* (SLIT-ROBO Rho GTPase activating protein 2) functions to control migration of neurons and dendritic formation in the cortex
- Gene has been duplicated three times in human and no other mammalian lineage
- Duplicated loci not in human genome

SRGAP2 Human Specific Duplication

SRGAP2C is fixed in humans

(n=661 individual genomes)

SRGAP2 duplicates are expressed

RNAseq

In situ

SRGAP2C duplicate antagonizes function

Example 2: Human-specific Duplication of *ARHGAP11B*

- Hypothesis: increase in number of basal radial glial cells or prolonged proliferation may lead to enlargement of the subventricular zone in humans
- Search for genes that are dramatically increased in concentration in basal radial glial cells as compared to neurons during development
- Only one gene of 56 not present in mouse

ARHGAP11B

Florea et al., Science 2015, Antonacci et al., Nat. Genet., 2014

ARHGAP11B induced gyrification of mouse brain

- E13.5 microinjection of *ARHGAP11B* induced folding in the neocortex by E18.5 in ½ of the cases— a significant increase in cortical area.

Transgenic human-specific duplicate *ARHGAP11B*: Marmoset fetal brain with human promoter

WT brain and brain expressing *ARHGAP11B* in neocortex (TG3). Arrowheads indicate cortical folds. R, rostral; C, caudal. Scale bars, 1 mm

- Increased the numbers of basal radial glia progenitors in the marmoset outer subventricular zone, increased the numbers of upper-layer neurons, enlarged the neocortex, and induced its folding.

Duplication of *ARHGAP11B* and 15q13.3 Syndrome

Chromosome 15

Duplication from *ARHGAP11A* to *ARHGAP11B* estimated to have occurred 5.3 +/- 0.5 million years ago.

Antonacci et al., *Nat Genet*, 2014,

Human-specific duplicated gene innovations and brain development

- *SRGAP2C*— 3.2 mya—produces a truncated protein that heterodimerizes with the parental product and alters neuronal migration, dendritic morphology and density of synapses ([Dennis et al., Cell, 2012](#); [Charrier et al., Cell, 2012](#)).
- *ARHGAP11B*— truncated duplicate is expressed in basal radial glial cells appears to expand neuronal count and expand subventricular zone ([Antonacci et al., Nat Genet, 2014](#); [Florio et al., Science, 2015](#)).
- *BOLA2B*--- (256 kya) duplication of gene family specifically at root of *Homo sapiens*, rapid fixation and largest difference between Neandertals and human genomes and is important in iron homeostasis ([Nuttall et al., Nature, 2016](#), [Gianuzzi et al., Am J Hum Genet 2019](#)).
- *NOTCH2NL*--- (<3 mya) partial duplication expressed in radial glial where interacts with NOTCH2 receptors and delays neuronal progenitor differentiation([Fiddes et al., Cell, 2018](#))
- Properties: Nearly fixed for copy number in the human population, predispose to disease instability and the duplications are incomplete with respect to gene structure. **NONE present in original human genome.**

Summary

- Interspersed duplication architecture sensitized our genome to copy-number variation increasing our species predisposition to disease—children with autism and intellectual disability
- Duplication architecture has evolved recently in a punctuated fashion around core duplicons which encode human great-ape specific gene innovations (eg. *NPIP*, *NBPF*, *LRRC37*, etc.).
- Cores have propagated in a stepwise fashion “transducing” flanking sequences---human-specific acquisitions flanks are associated with brain developmental genes.
- **Core Duplicon Hypothesis:** Selective disadvantage of these interspersed duplications offset by newly minted genes and new locations within our species. Eg. *SRGAP2C*

Overall Summary

- **I. Disease:** Role of CNVs in human disease—relationship of common and rare variants—a genomic bias in location and gene type
- **II. Methods:** NGS Read-pair and read-depth methods to characterize SVs within genomes—long-read genomes can now fully phase and assemble achieving complete telomere-to-telomere assembly
- **III: Evolution:** Rapid evolution of complex human architecture that predisposes to disease also coupled to gene innovation that makes us human

Disease

Evolution
